

# Warm Up

Draw an electron dot structure and structural diagram for the following:

a)  $C_3H_6$

b)  $PO_4^{3-}$

p. 225 #9-12

# Molecular Orbitals

When two atoms share electrons to form a molecule, their **atomic orbitals** combine to produce **molecular orbitals**.

↳ s, p, d ...

When the orbital is filled with two electrons, it is called a **bonding orbital**.

## Sigma bond ( $\sigma$ )

Bond that forms when two atomic orbitals overlap **head-on**.

-strong bond

## Pi bond ( $\pi$ )

"P"

Bond that forms when two atomic orbitals overlap **side-by-side**.

-orbitals overlap less than in sigma bonds, thus the bonds are **weaker** than sigma bonds.

# VSEPR Theory

## Valence-Shell Electron-Pair Repulsion Theory

Repulsion between electron pairs causes molecular shapes to adjust so that the valence-electron pairs are as far apart as possible.

Ex. CH<sub>4</sub>

**tetrahedral angle (109.5°)**

Ex. NH<sub>3</sub>

**Lone pairs (unshared pairs) also affect the shapes of molecules.**
