

## Warm Up

Determine the type of hybrid orbitals used by each carbon atom. State the total number of sigma and pi bonds.

p. 236 #23-29

29.

tetrahedral

# Worksheet 8.3

**Single bonds** $4sp^3 (s + p_x + p_y + p_z)$ 

- sigma bonds

tetrahedral, pyramidal, bent

**Double bonds** $3sp^2 (s + p_x + p_y)$ 

- 3 sigma bonds

 $p_z$ 

- pi bond

trigonal planar

**Triple bonds** $2sp (s + p_x)$ 

- 2 sigma bonds

 $p_y, p_z$ 

- 2 pi bonds

linear

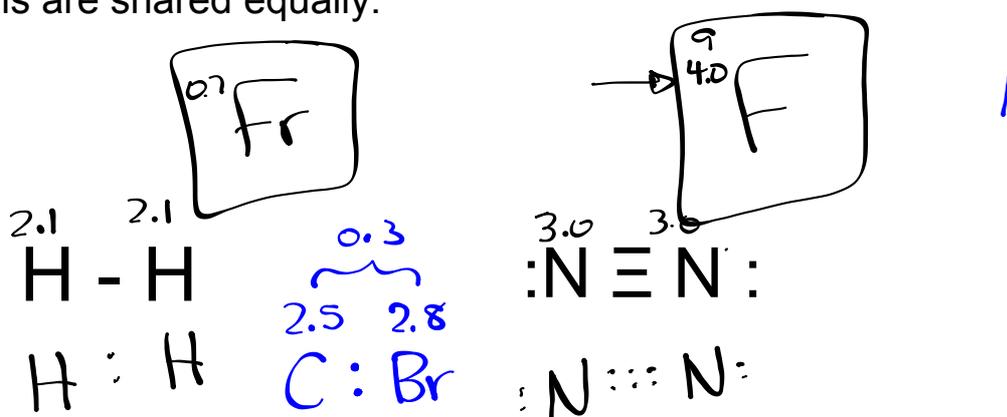

# Bond Polarity

- In covalent bonds, the bonding pairs of electrons are shared between atoms.
- Two nuclei 'pull' the electrons. Amount of 'pull' is dependent on the atoms' electronegativities.

## Nonpolar covalent bond

Bond that forms when the atoms in the bond pull equally, and the electrons are shared equally.

Ex.

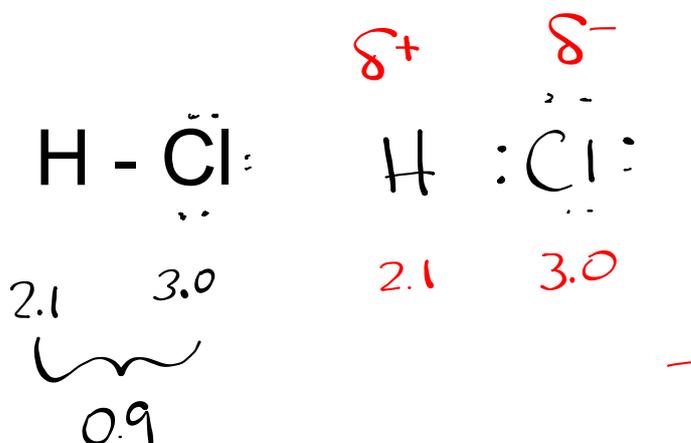

## Polar covalent bond

Bond that forms when the electrons are shared unequally

- More electronegative atom attracts electrons more strongly and gains a slightly negative charge. Less electronegative atom has a slightly positive charge.

Ex.

**Table 6.3 Electronegativity Differences and Bond Types**

<b>Electronegativity difference range</b>	<b>Most probable type of bond</b>	<b>Example</b>
<b>0.0-0.4</b>	<b>Nonpolar covalent</b>	<b>H - H (0.0)</b>
<b>0.4-1.0</b>	<b>Moderately polar covalent</b>	<b>H - Cl (0.9)</b>
<b>1.0-2.0</b>	<b>Very polar covalent</b>	<b>H - F (1.9)</b>
<b>≥ 2.0</b>	<b>Ionic</b>	<b>Na<sup>+</sup> Cl<sup>-</sup> (2.1)</b>

**\* No sharp boundary between ionic and covalent**
