Positron Emission

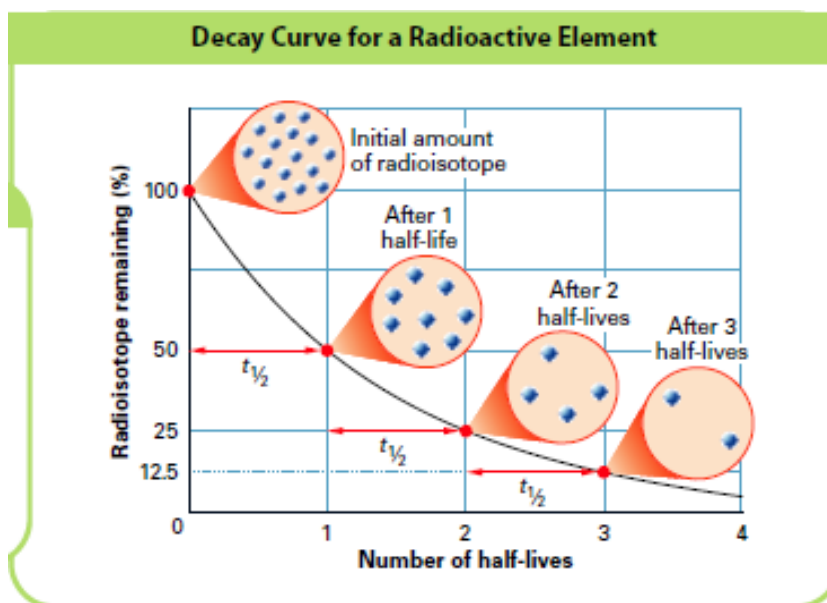

Alpha Emission

Half-Life

A half-life ($t_{1/2}$) is the time required for one-half of the nuclei of a radioisotope sample to decay to products. After each half-life, half of the existing radioactive atoms have decayed into atoms of a new element.

Sample Problem

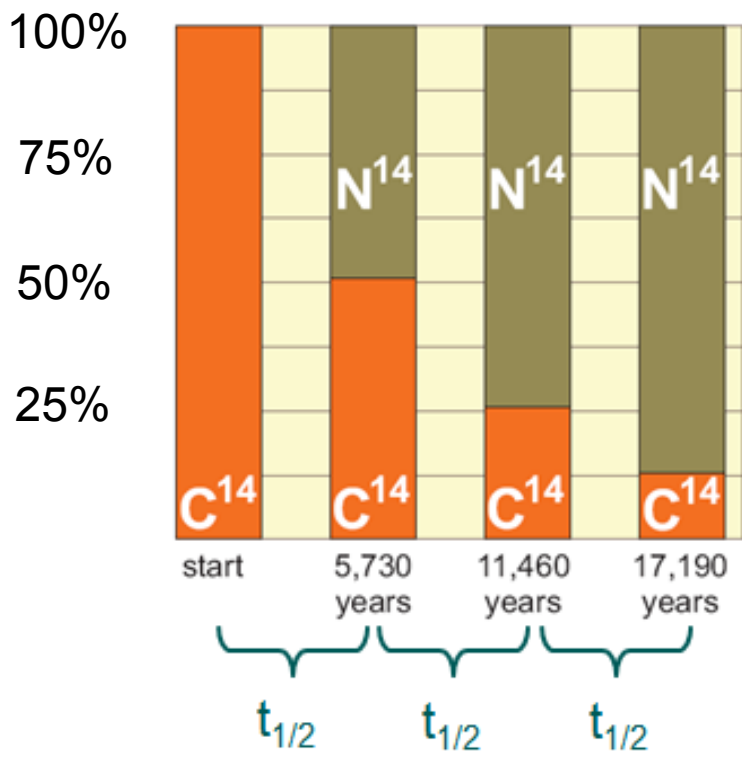

Carbon-14 emits beta radiation and decays with a half-life ($t_{1/2}$) of 5730 years. Assume you start with a mass of 2.00×10^{-12} g of carbon-14.

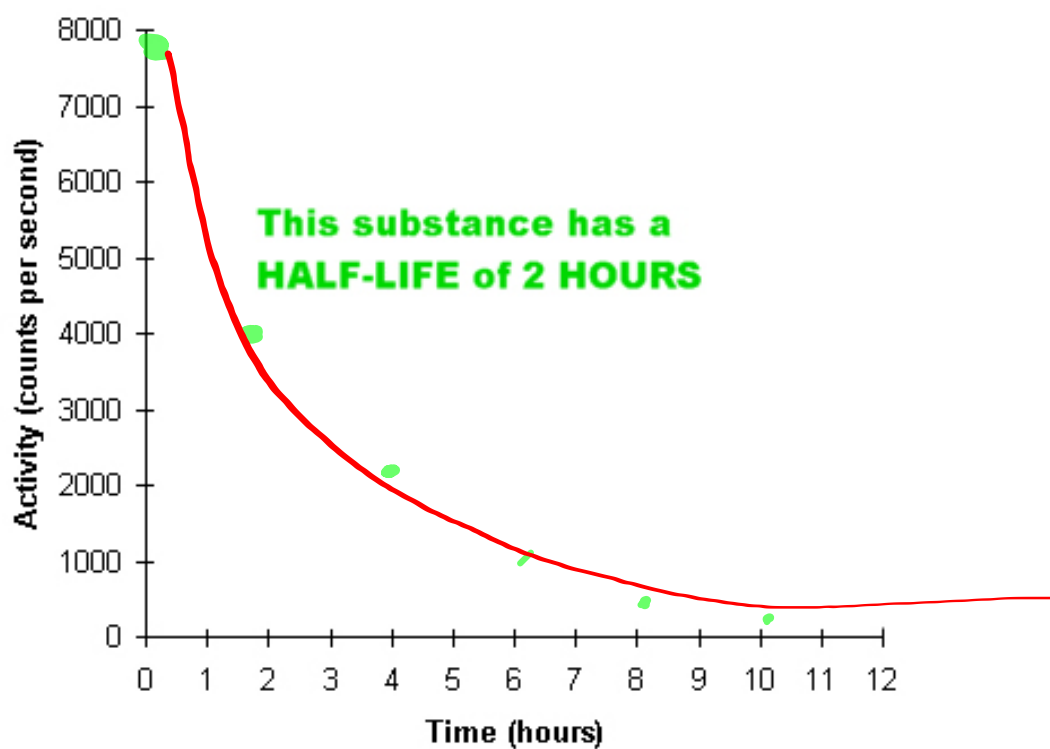

- How long is three half-lives?
- How many grams of the isotope remain after three half-lives?

$$a) \quad 5730 \text{ years} \times 3 = 17190 \text{ years}$$

$$b) \quad 2.00 \times 10^{-12} \text{ g} \times \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} =$$

$$\boxed{2.50 \times 10^{-13} \text{ g}}$$

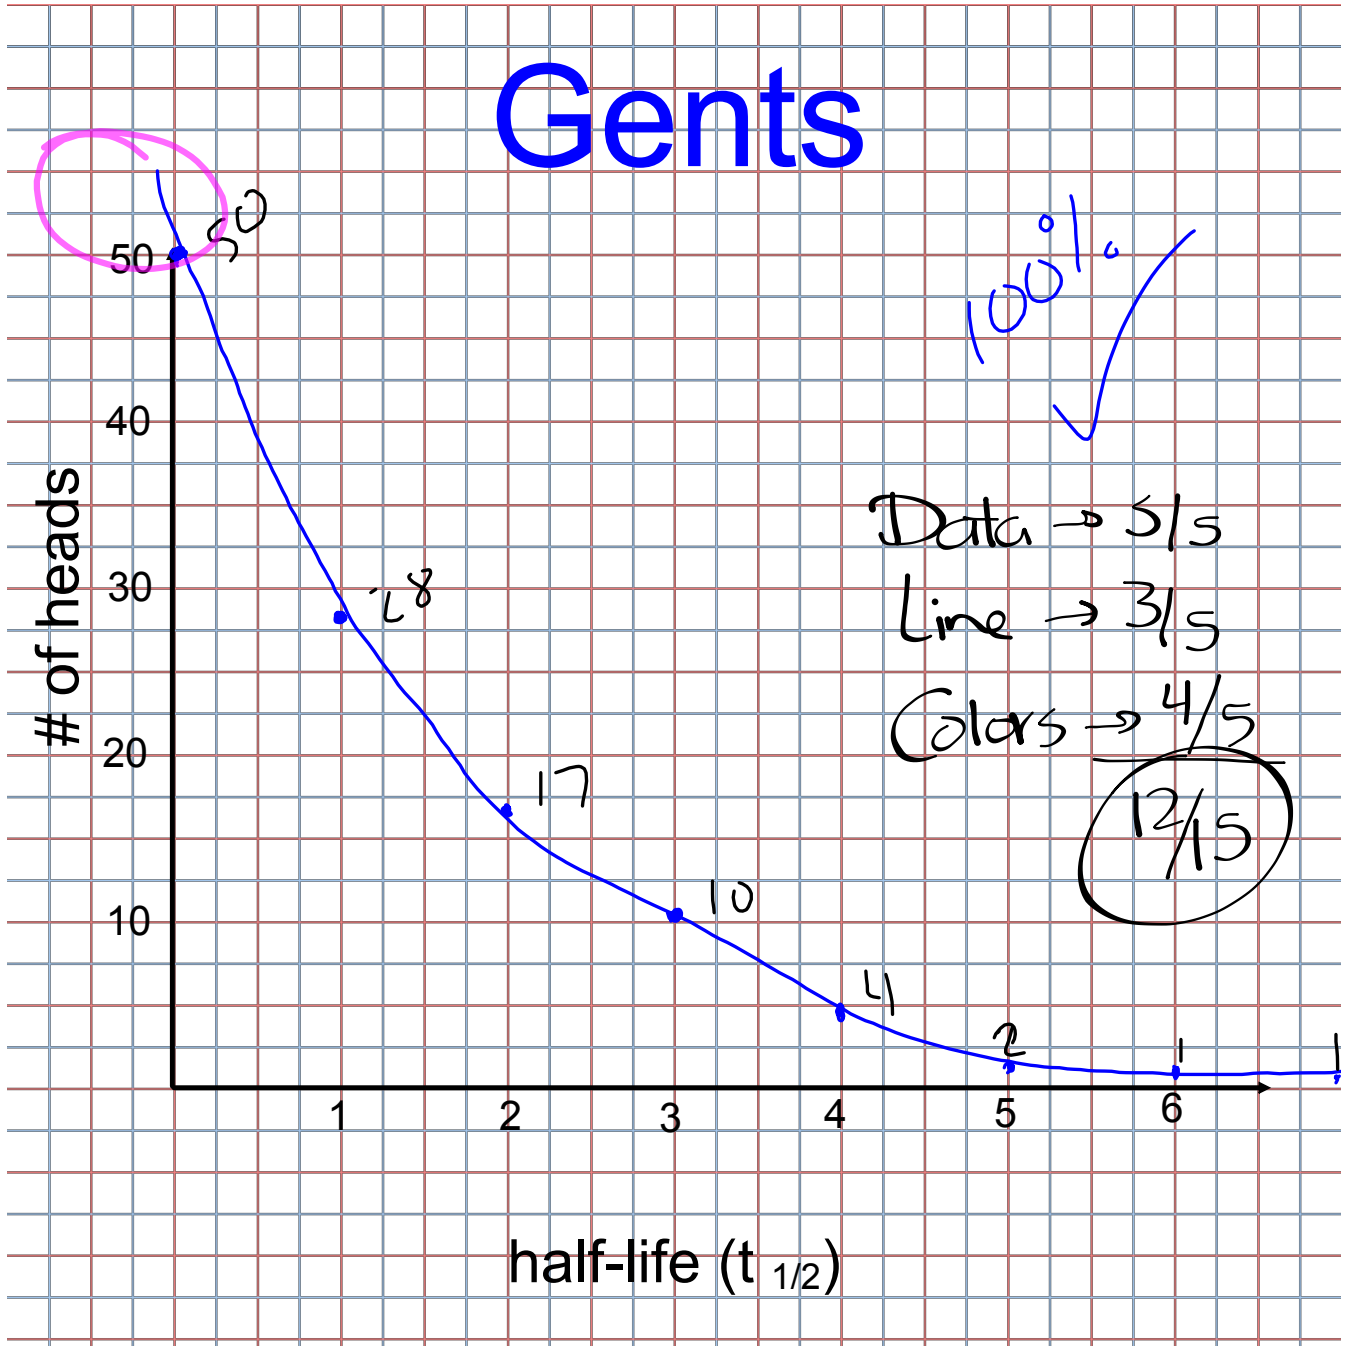

Coin experiment

Flip a coin 50 times, and plot the number of heads (y-axis), with the number of trials (x-axis).

Tails = decayed isotopes

Heads = remaining isotopes
